Coverage

Northstar Commerce continuously monitors corporate networks, production VPCs, VPN gateways, internet edges, DNS, and managed network services for potentially adverse events. The coverage register maps each network segment and service to an owner, telemetry source, and response queue.

Detection sources

Network detection sensors inspect east-west and north-south traffic in production. Firewalls, VPN concentrators, DNS resolvers, cloud flow logs, and secure web gateways forward events to the central SIEM. Health checks alert when a required telemetry source stops reporting for more than ten minutes.

Monitoring and response

The SIEM runs detections for unusual outbound volume, command-and-control indicators, impossible VPN travel, new internet-facing services, repeated denied connections, and changes to firewall rules. The on-call analyst triages alerts continuously, records disposition and affected assets, and escalates confirmed adverse events under the incident response plan.

Validation

Security Operations tests sensor coverage monthly using controlled connection attempts and reviews detection rules quarterly. The June coverage test produced events from all 18 registered network segments and all 42 monitored network services.
